Letter to the Editor

We read the article which was written by McGonaghy and Fosselman with great interest [1]. We do not agree with them in one subject. Especially in primary hyperhidrosis, the method we use is surgical treatment. We have achieved satisfactory results, and we have created many supporting publications on this subject [2-4]. One of them was the sudden increase in palmar heat during the intervention to the sympathetic chain during this operation. In the postoperative period, the hands and axillae were dramatically dry [2]. In addition, we protect the T2 ganglion by using our method and we could reduce the frequency of reflex sweating. We have shown this by applying a large group of patients [4]. This method was shown its effectivity of the operation. Of course, we recommend botox or other conservative applications for the patients who do not want surgery. As far as we observe, repetitive injections form a reluctance, especially in botox. We believe that the surgery is the gold standard in primary hyperhidrosis.
