A Survey of Complementary and Alternative Medicines Use in Out-Patient Paediatric Specialities and Pediatric Emergency Department

Department of Pharmaceutics and Head of Research, Oman Medical College, Oman

Abstract

Complementary and alternative medicine (CAM) is defined as the ‘diagnosis, treatment and or prevention which complements mainstream medicine by contributing to a common whole, by satisfying a demand not met by orthodoxy or by diversifying the conceptual framework of medicine. It is also identified as a general term which can be used to represent a group of diverse medical modalities, practices, and products [1]. WHO defines CAM as a broad set of healthcare practices that are not integrated into the dominant healthcare system. The use of complementary and alternative medicine (CAM) is widely documented in the literature. The concern is that CAM may interfere with mainstream medicine and it is difficult to know to what extent. Without knowing the extent, CAM use is prevalent in children, especially the vulnerable children. Little is known about the difference between healthy and chronically ill children with a focus on prevalence, reasons for use/non-use, costs, adverse effects (AE) and socio-demographic factors [2].

Cam popularity has risen in the last decade. Information about its use by pediatric patients in palliative care is still scarce [3]. The systematic review is available from 2000-2001 to estimate CAM prevalence in US. Through surveys on CAM in general, the average one-year prevalence of use of CAM was 41.1% and the average lifetime prevalence was 51.8%. Herbal medicine was the most popular CAM, followed by homeopathy, aromatherapy, massage and reflexology [4]. In addition, National estimates of the use of complementary health approaches among children aged 4–17 years in the United States is presented via this report Table 1 and 2. Selected modalities are compared for 2007 and 2012 to examine changes over time [5].

United States is using Complementary and alternative medicine (CAM) widely. It is used in conjunction with conventional medicine. Some CAM practitioners recommend against vaccination, and children who saw naturopathic physicians or chiropractors were less likely to receive vaccines and more likely to get vaccine-preventable diseases. Nothing is known about how child CAM usage affects influenza vaccination [6].

Examining the prevalence and predictors of complementary and alternative medicine (CAM) use was the purpose of some studies. Also, parental perceptions of CAM efficacy in a large, geographically diverse sample of children with Autism Spectrum Disorders (ASD) [7] was the subject of some studies.

The usage of complementary and alternative medicines in an outpatient pediatric neurology clinic, and to assess family attitudes toward the efficacy of complementary and alternative medicines versus prescription medications was studied as part of the research by some scientists Figure 1 and 2. Complementary and alternative medicine is an important element of the modern health
Moreover, many families incorporated different health belief systems. However, these studies were limited by cross-sectional design.

Use with decreased adherence to conventional asthma medicines. For pediatric asthma is increasing and previous studies linked CAM with conventional care to management of musculoskeletal problems. The users informed a physician about CAM use and side effects were rarely reported (4%) [12]. The study was conducted in Germany over a four week period in 2004 and they found that main reasons for use was to strengthen the immune system, physical stabilization and to increase healing chances/maintain health. Also, CAM use was high and most parents felt about the use of CAM amongst the children. One study indicated that CAM use was high among pediatric specialty clinic outpatients and was much greater in the western than in the central hospitals in Canada Table 3 and 4. Most respondents felt that their CAM use was helpful with few or no harms associated. The most common CAM products currently used were multivitamins/minerals, herbal products, and homeopathic remedies. The most common CAM practices currently used are massage, chiropractic, relaxation, and aromatherapy [11]. Use of complementary and alternative medicines (CAM) in children is general and is possibly increasing. The study was conducted in Germany over a four week period in 2004 and they found that main reasons for use was to strengthen the immune system, physical stabilization and to increase healing chances/maintain health. Also, CAM use was high and most parents would recommend certain CAM (94%). Moreover, 79% of the users informed a physician about CAM use and side effects were rarely reported (4%) [12].

Complementary and alternative medicine (CAM) is widely used in the European Union (EU) as suggested by studies. Herbal medicine was most commonly reported and CAM users were mainly women. In addition, the most common reason to use CAM was dissatisfaction with conventional care to management of musculoskeletal problems [13].

The use of Complementary and alternative medicine (CAM) for pediatric asthma is increasing and previous studies linked CAM use with decreased adherence to conventional asthma medicines. However, these studies were limited by cross-sectional design. Moreover, many families incorporated different health belief systems simultaneously to control asthma. As CAM use becomes more prevalent Figure 3 and 4, it is important for physicians to ask about CAM use in a nonjudgmental fashion [14]. One systematic review was done to estimate the prevalence and use of complementary and alternative medicine (CAM) in UK and was done between 1st January, 2000 to 7th October, 2011. The most popular CAM herbal medicine was followed by homeopathy, aromatherapy, massage and reflexology. In addition, healthcare professionals should responsibly advise their patients about the use of CAM [15].

Complementary and alternative medicine therapies are associated with mental health in post disaster environment and interview was done between 2010 and 2012 as a cross-sectional study. The most common CAM therapies were multivitamins, aromatherapy and massage and were protective for depression [16].

Complementary and alternative therapies are used in cases of childhood cancer. One study was done by cross-sectional design, questionnaire and face-to-face interviews. They found that the mean age of the children was 8 years and prevalence of use of CAM among parent’s children with cancer was not negligible. In addition, the researchers’ belief that health professional must be informed about the use of CAM and its methods and given information about use of CAM with conventional treatment [17]. On the other hand, adverse event has been inconclusive with some CAM herbals which were used to treat disease for example, Aloe vera in the treatment of psoriasis, cranberry in cystitis prevention, echinacea for the prevention of common cold and pomegranate for the prevention/treatment of cardiovascular problems [18].

Increasing interests to complementary and alternative medicine (CAM) are seen in chronic inflammatory bowel disease (IBD) that conventional therapies do not show any symptomatic relief or control disease and may cause side effects [19].

More than 30% of patients do not respond to pharmacologic interventions for headache, so as a result such patients started to utilize CAM therapy to manage headache and avoid side effects of medication. Examples include nutritional therapies like herbal remedies and vitamin or mineral supplementation and relaxation therapy, biofeedback therapy, cognitive-behavioral therapy which were included as behavioral treatments [20,21]. The identification of Complementary and alternative medicine (CAM) as therapy that is not included under conventional medicine was used to treat multiple sclerosis (MS) patients but because of the complexity and potential severity of the disease, parents were advised to be careful to use it.

Hence, we can conclude that physicians need to understand and know about the use of CAM amongst the children.

Objectives of the Study

The objectives of the present study were

To study the effect on the patients and learn how to avoid this.

To identify the type of CAM that is being used.

To study its effect on the patients and learn how to avoid this.

Experimental

Type of study: The present study was a cross-sectional survey of children attending out-patient pediatrics clinic and pediatric emergency department at the tertiary care hospital specialty.
The Questionnaire was administered to the parents and face-to-face interviews were conducted. The initial English version of the questionnaire was initially obtained from the literature which was translated to Arabic by the two researchers and section of it was back translated between the two researchers to ensure accuracy of translation. (There exists no standard survey instrument for assessing pediatric CAM; however, the questionnaire for this study was designed using different surveys used in the literature.)

**Hypothesis:** CAM interferes with mainstream medicine.

**Subjects and settings:** This study was intended to measure the prevalence of complementary and alternative medicine (CAM) use in out-patient pediatric specialties at a tertiary care hospital and explore types of CAM use in Oman. All patients attending the out-patient and emergency departments at a tertiary care hospital (Royal hospital) were asked to participate in the study over 1 week in July 2016. 158 patients/guardians were informed about the purpose of the study and were interviewed.

Approval from the Research and Ethical committee, Royal Hospital: Prior to data collection, a research application form was completed and submitted to the Research and Ethical review committee of tertiary care hospital (Royal Hospital). The proposal was approved by the tertiary care hospital Ethical review committee.

**Data Collection and Statistical Analysis**

**The data collection was done at the Royal hospital**

The data was obtained through the survey (questionnaires) and was analyzed descriptively using frequency table and cross tabulation and graphically using charts. Chi-square test of independence was also used to obtain inferential conclusions about any two variables of interest. These methods and tests were conducted using statistical package for the social sciences (SPSS). The questionnaire used is shown in Appendix 1.

**Results**

Data collection was commenced after obtaining the approval by Royal hospital. Patients who visited the out-patient department between 17th July, 2016 and 25th July, 2016 at the out-patient and emergency department were approached and requested to complete the questionnaires. In pediatric clinic, 117 patients visited as out-patients and 41 patients visited emergency department.

Table 1 shows the number of people attending to out-patient and emergency departments. 117 (74.1%) patients attended the out-patient department and 41 (25.9%) patients attended the emergency department.

**Discussion**

1. 36.6% of the patients used olive oil. Hence it was considered as the most common of all CAM used.
2. 63.3% of the patients used CAM for treatment/ symptom relief as a reason for CAM use.
3. 71.5% of the patients felt that the effect of CAM use was excellent.
4. 76.6% of the patients were completely satisfied after CAM use.
5. 99.4% of the patients did not face any adverse reaction/ events after using CAM.
6. 74% of the patients attended OPD department, while 25.95% of the patients attended ER department.
7. 64.56% of the patients were without previous prescribed medication, while 35.44% of the patients were on medication.
8. 63.29% of the patients were males and 36.71% were females.
9. About 35% of the patients were from Muscat.
10. 63% of the patients were visiting the hospital with pre-existing diseases, while 36.94% were not visiting with pre-existing diseases.
11. 34.62% of the patients were being informed about CAM use, while 65.38% were not.

**Conclusion**

We can conclude that highest amount of CAM use was of Olive oil and majority of paediatric patients did not experience any adverse effect. Further research on a broader scale is needed and maybe at different time of year as there might be seasonal use of CAM.
