## **Keywords**

Bell's phenomenon; Lash ptosis; Levator function; Marginal reflex distance; Ptosis

## **Clinical Image**

A 77-year-old woman presented with bilateral eyelid and eyelash ptosis. Her complaints have increased over the last two years. In the ocular examination, the corrected visual acuities were 20/20 bilaterally. The intraocular pressures were 17 mmHg in the right eye and 18 mmHg in the left. There was bilateral eyelid ptosis accompanied by lash ptosis. The marginal reflex distance-1 was measured 1.5 mm in the right eye and 2 mm in the left eye. Levator functions were found 10 mm in both eyes. Bell's Phenomenon was existed in both eyes. Lash ptosis or eyelash ptosis is a drooping or declining of the upper eyelashes. It results from the anatomical changes in the eyelid. It has been reported an association with floppy eyelid syndrome, congenital ichthyosis, acoustic neuroma and latanoprost usage. This condition is sometimes together with eyelid ptosis. The management of lash ptosis is generally surgical. The surgical approaches depend on the severity and the accompanying conditions such as eyelid ptosis or blepharoptosis. The main purpose is to rotate the lash line upwards using sutures. Finally, a surgical treatment including eyelid and eyelashes ptosis was recommended to this patient (Figure 1).
